

Report: Relationship between life expectancy and health spending in percentage of GDP in 2020

Laurent Desmet

17/05/2025

There is a **weak positive relationship** between total health spending as a percentage of GDP and life expectancy in 2020. Countries spending a higher share of GDP on health tend to have somewhat higher life expectancy, but the relationship is not very strong.

The Pearson correlation is $r = 0.28$, with $R^2 = 0.08$, meaning health spending as % of GDP explains only about **8%** of the cross-country variation in life expectancy in this dataset. This suggests that many other factors also matter, such as income level, health system efficiency, inequality, public health conditions, conflict, demographic structure, and spending per person.

Personal reflection on the use of ChatGPT for data analysis

It was surprisingly easy to use ChatGPT for data analysis. I am curious however if these tools can also be used to further investigate certain results. For example trying to find mechanisms behind certain findings, building frameworks etc.

It was surprising that the plots ChatGPT developed were interactive.
